**Date :** November 29, 2013

Here are two photos from *N. viridiflorus* which flowered at October 14 near La Roche and two from today in my green house. The petals of the flowers are more or less reflexed. Crosses of viridiflorus hybrids like Emerald Sea with *N. triandrus* and *N. cyclamineus* to strengthen this effect are easily possible. The style is exserted or deep in the flower.

---

The colour reaches from green to nearly yellow. The cup is sometimes strongly splitted and therefore crosses with standard split corona daffodils may be interesting. The intense fragrance can be transmitted to most descendants. The flowering period for a maximum temperature of 26 C during the day and a minimum of 15 C in the night as in La Roche is normal for daffodils, but for temperatures of 15/10 C it is one week or more. This is similar for many crosses. Therefore daffodils which flower for a long time can be produced. The flowering time is autumn or the begin of winter for most crosses.

Some of these characters you find in existing *viridiflorus* hybrids. But I think there is much to do in hybridizing to get more and different daffodils of this type.

If anybody is interested in receiving some seed grains of *N. viridiflorus*, please let me know.
